Abstract: Another of the tried-and-true psychological faults that leads to traffic deaths is drowsy driving. According to investigations, drivers' eyelids started flashing differently right before collisions. The flicker of something like the eye is often the primary indicator of exhaustion. A same method may be used by the system to determine sleeping disruption symptoms and the beginning of driving tiredness. The blockiness and sleepiness of the driver progressively start as their level of exhaustion rises. A's motivation to operate a motor vehicle securely is decreased and their chance of making a mistake that might cause an incident rises when they are sleepy. In this study, we created a system that use an Infrared sensor to track irregularities in motorists' eye movements. A siren warns the motorist if any anomalies are discovered. This initiative may assist in tracking comatose patients at all moments in addition to identifying driver sleepiness; when a person awakens from a coma, an automated buzzer will sound. Using the electric circuits design tool schematic capture suite, simulations is evaluated.
